ABSTRACT

A healthy diet supports energy needs and provides for human nutrition without exposure to toxicity. Tea has received a great deal of attention because tea polyphenols are strong antioxidants, and tea preparations have shown inhibitory activity against tumorigenesis. It is consumed in different forms namely green, black and oolong tea. Tea is used in the management of different types of cancers including Oral Cancer. Micronuclei (MN) act as a cancer biomarker. The present review focuses on the antioxidants of various tea and their mechanism of protective effects on oral cancer.

KEYWORDS: Tea, Polyphenols, Micronuclei, Oral Cancer.

INTRODUCTION:

The word “diet” often implies the use of specific intake of nutrition for health. The requirements for a healthy diet can be met from a variety of plant-based and animal-based foods. A healthy diet supports energy needs and provides for human nutrition without exposure to toxicity. More and more research is finding that diet plays a crucial role in the prevention of cancer. A joint WHO/FAO Expert Consultation report has estimated that dietary factors account for approximately 30% of cancers in industrialized countries[1]. There is convincing evidence that being overweight and obese increase the risk of cancer. The World Cancer Research Fund has made the following dietary recommendations[2-5]:

- Increase fruit and vegetable intake - at least 5 portions per day.
- Consume a high proportion of high fiber foods such as whole meal bread and other cereals
- Choose a variety of plant based foods such as cereals, legumes (such as lentils, beans and peas), starchy foods (such as pasta, rice and bread) as well fruit and vegetables
- Select foods low in fat and salt
- Drink alcohol in moderation if at all.

These dietary changes as well as maintaining a healthy weight and being physically active can help reduce the risk of developing cancer. There is increasing evidence that specific substances found in certain foods can enhance general healthy eating recommendations e.g. phenolic compounds found in plants. Tea is rich in specific phenolic compounds including flavonoids. Tea is one of the most widely consumed beverages in the whole world, second only to water, and its medicinal properties have been widely explored. It is believed that tea originated from China around 2737 B.C., although earliest documented evidence as mentioned in a Chinese dictionary can be traced back to 350 B.C.[6]. Tea was brought to Europe in 1559 A.D. The tea plant, Camellia sinensis, is a member of the Theaceae family. The three major forms of tea black, green and oolong are produced from the leaves of the tea plant. Tea leaves are dark green in colour, alternately arranged, oval in shape and have serrated edges. Green tea beverage extract is attributed to the chlorophyll content. A cup of green tea contains about 80 polyphenols, which are essentially colorless lactones, hydrocarbons etc. (aldehydes, alcohols, esters, lactones, hydrocarbons etc) and volatile organic compounds (aldehydes, alcohols, esters, lactones, hydrocarbons etc)[7]. The yellowish green color of the unoxidized extract is attributed to the chlorophyll content. A cup of green tea contains about 300 to 400 mg of polyphenols, which are essentially colorless. Of the polyphenols, epigallocatechin gallate (EGCG) and epigallocatechin (EGC) are the most important and it is estimated that a typical cup of green tea contains 10 to 30 mg of EGCG. Several epidemiological studies as well as studies in animal models have shown that green tea can offer protection against various cancers such as oral, skin, breast, prostate and lung[8].

OOLONG TEA: An Overview

Oolong tea also known as blue green tea or wu long tea is produced by partial fermentation of tea leaves from the plant Camellia sinensis. This process is repeated several times until the desired level of oxidation is achieved. It contains catechins, theaflavins and other polymerized catechin derivatives but the amount of catechin content is less than that of green tea. Tea leaves also contain flavonoids, such as quercetin and myricetin, as well as nitrogenous compounds, such as caffeine and theobromine. Caffeine accounts for 2-5% of the water-extractable material in green, oolong, and black tea. Many health benefits including prevention of cancer, hepato cellular carcinoma, etc have been ascribed to the consumption of this beverage.

GREEN TEA: An Overview

Green tea and its constituent catechins are best known for their antioxidant properties, which has led to their evaluation in a number of diseases such as cancer associated with reactive oxygen species (ROS). The chemical composition of green tea is complex. It contains proteins (15-20% dry weight), the amino acids constituents of protein such as theanine or 5-N-ethylglutamine, glutamic acid, tryptophan, glycine, serine, aspartic acid, tyrosine, valine, leucine, threonine, arginine, and lysine and contributed towards (1-4% dry weight); carbohydrates (5-7% dry weight) such as cellulose, pectins, glucose, fructose, and sucrose; minerals and trace elements (5% dry weight) such as calcium, magnesium, chromium, manganese, iron, copper, zinc, molybdenum, selenium, phosphorus, cobalt, strontium, nickel, potassium, fluorine, and aluminum; and trace amounts of lipids (linoleic and α-linolenic acids), sterols (stigmastanol), vitamins (B, C and E), xanthic bases (caffeine, theophylline etc), pigments (chlorophyll, carotenoids etc) and volatile organic compounds (aldehydes, alcohols, esters, lactones, hydrocarbons etc)[9,10]. The yellowish green color of the unoxidized extract is attributed to the chlorophyll content. A cup of green tea contains about 300 to 400 mg of polyphenols, which are essentially colorless. Of the polyphenols, epigallocatechin gallate (EGCG) and epigallocatechin (EGC) are the most important and it is estimated that a typical cup of green tea contains 10 to 30 mg of EGCG. Several epidemiological studies as well as studies in animal models have shown that green tea can offer protection against various cancers such as oral, skin, breast, prostate and lung[11].

BLACK TEA: An Overview

Black tea is made from leaves that have been withered before being rolled and dried[12]. Quantitatively, black tea is the major type of tea produced worldwide[13]. In black tea, catechins, theaflavins (TF) and thearubigins (TR) accounts for 3-10, 2-6 and >20% respectively. Theaflavins consist of two catechin molecules joined together and account for about 10% of the converted catechins, whereas the thearubigins are more complex flavonoid molecules, whose structural chemistry are still unknown, and may account for up to 70% of flavonoids in black tea[14]. Researchers from New Jersey, USA have shown that theaflavin-2 (TF-2), a compound unique to black tea and oolong tea kills cancer cells. Theaflavin-2 suppresses the activity of a gene that induces the inflammatory enzyme cyclooxygenase (COX 2), while also reducing the activity of other inflammatory molecules such as TNF-α and nuclear factor-kappa B (NF-KB). Theaflavin-2 was also shown to produce a pattern of gene regulation similar to that found in the cancer cells.

ORAL CANCER and TEA:

Oral cancer is the sixth most common human cancer, representing 3% of all types of cancer. They are located in the oral cavity in 48% of cases, and 90% of these are oral squamous cell carcinoma. They are sometimes preceded by precancerous lesions, such as leukoplakia and erythroplakia. More than 300,000 new cases of oral squamous cell carcinoma are diagnosed annually. The most common site for intraoral carcinoma is the tongue, which accounts for around 40% of all cases in the oral cavity proper. Tongue cancers most frequently occur on the posterior-lateral border and ventral surfaces of the tongue.

ACKNOWLEDGEMENTS:

We have screened 311 subjects from different areas of Eastern, North Eastern India and also from RKMSP Hospital, Kolkata. 61.09% had betel quid chewing habit. Percentage of micronuclei is higher than the normal in cases who had betel quid chewing habit. Black tea without milk is very much effective for oral cancer. 81.03% had black tea drinking habit. Overall tea is an affordable beverage of natural origin, shown some preventive effect and also reducing the risk of cancer.

REFERENCES:

CONCLUSION:

The process of formation of oral cancer results from multiple sites of premalignant changes in the oral cavity. Micronuclei act as a biomarker of squamous cell carcinoma. Percentage of MN formation has been observed in pre-cancerous lesions of the oral cavity of betel quid chewers. The polyphenols present in tea decrease the risk factor of specific type of cancers by inducing phase I and phase II metabolic enzymes that increase the formation of carcinogens.

We have screened 311 subjects from different areas of Eastern, North Eastern India and also from RKMSP Hospital, Kolkata. 61.09% had betel quid chewing habit. Percentage of micronuclei is higher than the normal in cases who had betel quid chewing habit. Black tea without milk is very much effective for oral cancer. After supplementation of black tea micronuclei percentage are lower than before. Overall tea is an affordable beverage of natural origin, shown some protective effect and also reducing the risk of cancer.

ACKNOWLEDGEMENTS:

This investigation was supported by the grants from National Tea Research Foundation (NTRF) Tea Board, Kolkata, India. I am thankful to my PhD guide Prof (Dr.)Madhusnata De and also Dept of Maxillofacial and ENT Department of RKMSP Hospital, Kolkata, India.
